

NewsGP article outline- Should children get the COVID vaccine?*

Associate Professor John Litt AM retired academic GP and public health physician, co-lead CoRiCal COVID risk calculator

Dr Tej Shukla Cairns Hospital, University of Queensland and Infectious Diseases Trainee in the Queensland Network

Dr Olivia Williams GP, public health physician, and researcher, School of Public Health, Uni of Queensland

Dr Andrew Baird GP, Melbourne

** All co-authors are CoRiCal team members who have contributed to the development of CoRiCal, a COVID Risk calculator*

1. Are all children at risk from getting COVID?

Yes. While a sizable proportion of children (82% in the Australian PAEDS SARS-COV-2 Serosurvey conducted in 2022) (1) have had COVID, immunity against re-infection is short-lived in children who have had COVID-19 or who have been vaccinated (2).

The Omicron variants of COVID-19 are more transmissible than the original strain and earlier variants (3). They are causing more cases in children, but they are not causing more severe disease. Children are most likely to catch COVID-19 from household or close family contact with infected adults (4).

2. Can COVID be a serious health issue in children?

Children tend to get mild disease and most do not need to go to hospital, especially since the emergence of the Omicron variant (5). The incidence of hospitalization was reduced by two-thirds in children who have had a COVID vaccine during the Omicron period (6). Rarely, around 1 in 3000 children infected with COVID-19 develop a post-COVID multi-inflammatory syndrome (MIS-C) that affects many organs in their body (7). The incidence of Multi Inflammatory Syndrome in children (MIS-C) in the Australian setting, when omicron has been circulating, is 8 cases per 100,000 children who have had omicron COVID (8). Two doses of the Pfizer COVID vaccine prevented 84% of MIS-C cases in patients ages 5–18 years (7). Another study showed that the incidence of MIS-C following a COVID vaccine in older children (age 12–20 years) was 3 per ten million children vaccinated against COVID (in those who have not had COVID) (9)

Long COVID in children is possible but there is considerable debate about its nature and extent in children (10, 11).

3. Can children spread COVID to other children and vulnerable adults?

Yes, but so can other people also spread COVID to these groups (4). The more challenging ethical issue is whether (and by how much) vaccination reduces the risk of transmission of COVID from children to vulnerable others, and therefore whether children should be vaccinated to reduce spread, especially when the risks from COVID are much less in children (12, 13).

4. Should all children get vaccinated against COVID?

Yes. *Vaccination is recommended for everyone in Australia aged 5 years and over. Vaccination is also recommended for children aged 6 months to under 5 years who are severely immunocompromised, or have disability, as well as those who have complex and/or multiple health conditions that increase their risk of severe COVID-19*(<https://www.health.gov.au/our-work/covid-19-vaccines/who-can-get-vaccinated/children>). Despite this clear advice from the Department of Health, Australian Government, the WHO has recently 'downgraded' children as a priority group to get a COVID vaccine (<https://www.who.int/news/item/28-03-2023-sage-updates-covid-19-vaccination-guidance>). WHO do state that *primary and booster doses are safe and effective in children and adolescents. However, considering the low burden of disease, Strategic Group of Experts on Immunization (SAGE) urges countries considering vaccination of this age group to base their decisions on contextual factors, such as the disease burden, cost effectiveness, and other health or programmatic priorities and opportunity cost.* They also indicate that COVID vaccines in children should not be at the expense of administering traditional essential vaccines for children – such as the rotavirus, measles, and pneumococcal conjugate vaccine.

Every year in the United States, prior to the availability of a vaccine, 3 children died of hepatitis A virus, 8 children died of meningococcus, 16 children died of varicella, 17 people of all ages died of rubella, and 20 children died of rotavirus. Between October 2020 and October 2021, 66 children in the United States aged 5 to 11 years died of SARS-CoV-2 infection (14).

5. What are the main risks of the COVID vaccine in children?

Local side effects are fairly common. Children are likely to experience mild side effects, such as fever, fatigue/sleepiness and pain at the injection site after vaccination, but these usually resolve within 48 hours (15). More serious, but uncommon adverse effects include myocarditis. This mostly occurs after the second dose of an mRNA vaccine in males under age 40 years, but it can occur at any age, and in

both sexes (16). Myocarditis is inflammation of the heart. There are many possible causes of myocarditis. COVID-19 can cause myocarditis in some people. When omicron has been circulating the incidence of myocarditis in children who have had COVID is ~1 in 250 (17). This incidence is much higher than after an mRNA COVID vaccine. Data from 40 healthcare systems participating in a large network found that the risk of cardiac complications was significantly higher after SARS-CoV-2 infection than after mRNA COVID-19 vaccination for both male patients and female patients in all age groups (18).

6. Does vaccination against COVID in children provide a longer duration of immunity when compared with the child getting COVID?

There is good evidence, in adults, that hybrid immunity (ie immunity from both vaccination and past infection) provides a higher level of protection against COVID. Recent studies suggest that hybrid immunity provides some protection against infection for at least seven or eight months (19). This means that individuals who have had wild COVID will get a better level of protection by having a COVID vaccine (20).

We await evidence about whether a similar benefit to hybrid immunity is seen in children. There is also no data available the about long-term protection after both natural infection and vaccination in children (21).

In a British study, primary Omicron infection elicited a weak antibody response and only 53% of children developed detectable neutralizing antibodies. Vaccination elicited the highest levels of antibody response and was also strongly immunogenic following prior natural infection with Omicron. The investigators concluded that *'vaccination may represent the most effective approach to control infection whilst cellular immunity should offer strong clinical protection'* (22).

7. What tools and aids are available for parents to assess the risks and benefits of their child getting a COVID vaccine?

Several tools are available to help parents work through the costs and benefits associated with a child getting a COVID vaccine. The COVID Risk Calculator (CoRiCal) team (which includes academics and clinicians from four Australian Universities (Flinders University, University of Queensland, QUT and Sydney University) has successfully built a Bayesian network modelling frameworks for risk-benefit

analysis of COVID-19 vaccines in Australia (23). The recently released children's version of CoRiCal can incorporate multiple sources and types of evidence, and assumptions can be rapidly updated. Model outputs are publicly accessible through the web-based calculator which is supported by the Immunisation Coalition (<https://corical.immunisationcoalition.org.au/>) that enables users to define scenarios (age, sex, vaccination status) and see personalised risk-benefit outputs (e.g., developing myocarditis from vaccine vs from SARS-CoV-2 infection). CoRiCal can be used by individuals, or for facilitating shared decision making between clinicians and patients or parents.

The National Centre for Immunisation Research and Surveillance (NCIRS) has also developed a decision aid for parents with children who wish to look at the costs and benefits of their child having a COVID vaccine (see <https://ncirs.org.au/covid-19-decision-aid-for-children>).

Potential additional questions

8. What countries are recommending a COVID vaccine for children?

About 120 countries have approved COVID-19 vaccines for children, but at different ages (24). Some notable exceptions include: the UK, and some Scandinavian countries (25).

9. If a child had had COVID, should they get a COVID vaccine?

Yes the Department of Health(<https://www.health.gov.au/our-work/covid-19-vaccines/who-can-get-vaccinated/children#if-your-child-has-had-covid19>) has suggested that:

If (a) child has had COVID-19 you should wait 3 months after the confirmed infection before they have a COVID-19 vaccine dose.

This is to optimise their vaccine protection. A longer gap between infection and vaccination is likely to lead to a better immune response and result in longer protection from reinfection.

The next scheduled dose of COVID-19 vaccine should be given as soon as possible after 3 months. (The child) should still have all the recommended doses.

As highlighted above, there are benefits from hybrid immunity so a child's level of protection is likely to be enhanced if they have a COVID vaccine some time following a bout of COVID.

10. Can my child get a COVID vaccine at the same time as their routine childhood vaccines?

The Department of Health (<https://www.health.gov.au/our-work/covid-19-vaccines/who-can-get-vaccinated/children#covid19-vaccines-and-other-vaccines>) has provided specific advice about co-administering a COVID vaccine with other routinely administered childhood vaccines.

For children aged 5 to 11, they suggest that:

If a child has had COVID-19, you do not need to defer other vaccinations – for example, the flu vaccine. But they should not get any vaccine if they are acutely unwell (e.g., have a fever).

For children aged 6 months to under 5 years, they recommend:

You should wait 7-14 days between the child's COVID-19 vaccine and other vaccines to minimise the risk of adverse events such as fever.

The COVID-19 vaccine can be administered with other vaccines in special circumstances, such as with outreach programs to remote areas, or children receiving complicated catch-up schedules.

Australian Technical Advisory Group on Immunisation (ATAGI) has made recommendations on the use of COVID-19 vaccines in Australia, including co-administration.

'There is limited evidence on the safety and effectiveness of co-administering COVID-19 vaccines at the same time as other vaccines. Providers need to balance the opportunistic need for co-administration with the benefits of giving the vaccines on separate visits. There is the potential for an increase in mild to moderate adverse events when more than one vaccine is given at the same time. Co-administration or near administration (e.g., within days) with another vaccine may also make it challenging to attribute potential adverse events. Providers should ensure that parents/guardians of young children receiving COVID-19 vaccines are aware of the increased potential for local reactions'. (<https://www.health.gov.au/our-work/covid-19-vaccines/advice-for-providers/clinical-guidance/clinical-recommendations#timing-of-administration-of-other-vaccines-including-influenza-vaccine>, last updated 23rd March 2023)

[word count 11.4.23- 1594]

Table. Summarising the pros and cons of vaccinating healthy children against COVID (assuming majority of cases are due to Omicron variants) (12, 25-28)

Pros	Cons
<p>Reasonable likelihood of getting COVID</p> <ul style="list-style-type: none"> - While global burden of disease in children is low, it is not negligible. - Nearly two-thirds of children hospitalised with COVID have no underlying conditions 	<p>Children have fewer and milder symptoms than adults</p>
<p>Some impact on reducing community transmission of COVID</p>	<p>Impact on transmission is uncertain</p>
<p>Effective in reducing the likelihood:</p> <ul style="list-style-type: none"> - Getting COVID - Being hospitalised due to COVID - Severe COVID - Multi Inflammatory Syndrome in Children: Vaccinating children who have had COVID may have improved (hybrid) immunity 	<ul style="list-style-type: none"> - Adverse effects of vaccination eg myocarditis - Large proportion of children have had COVID so have some level of immunity - Imprinting associated risk
<p>Long COVID</p> <p>Long COVID in children is possible but there is considerable debate about its nature and extent in children</p>	
<p>COVID vaccines are safe</p>	<p>Long term safety of vaccines unknown</p>
<p>Impact on routine childhood vaccinations</p> <ul style="list-style-type: none"> - routine childhood vaccinations provide an opportunity to vaccinate against COVID 	<p>Impact on routine childhood vaccinations</p> <ul style="list-style-type: none"> - may be delayed
<p>Helps to minimise school disruption</p>	<p>Vaccination is only one component in keeping schools safe</p>
<p>Impact of new variants uncertain</p>	<p>Risk to undermining trust in vaccination</p>
<p>Recommended COVID vaccines in children are provided free to parents</p>	<p>Vaccine cost</p>
<p>Endemicity</p> <ul style="list-style-type: none"> - In the context of endemic disease, leaving children unvaccinated provides a potential reservoir for the emergence of new variants 	<p>Endemicity</p> <ul style="list-style-type: none"> - Most COVID disease is mild in children, leaving them as a potential reservoir would result in mild primary infection and a natural booster of immunity in adults
